1) Full Keels. This particular keel by design covers at least half of the boat's hull. It contains a forward edge which bends upwards while its aft edge usually links to a rudder. This type of keel has a key advantage of providing directional stability as well as safe and strong grounding of the boat or ship.

Older designs with longer lower aspect keels have a much greater mounting area than modern high aspect ones and are more likely to survive a grounding without damage. I suspect we will see increasing keel problems with modern "performance oriented" boats as they get older, having been battered...

The keel is the structural backbone of the vessel, and the fin hangs from it. Fish have both backbones and fins; so do yachts. A well-designed fin, in conjunction with a skeg-hung rudder, can provide excellent directional

stability, handiness, reduced wetted area and improved weatherliness.

A boat with keel-attached rudder, carrying a small amount of weather helm, say 3° to 5° , does, in effect, cause the keel and rudder in combination to become asymmetrical on either tack, providing beneficial lift at the expense of slight detrimental drag. Recovering from a Stalled Keel. To recover move the rudder back to amidships. The water flow now meets the rudder at an angle from the downwind side, creating lift to windward and so turning the boat downwind. This turns the boat more into line with the water flow, reducing the angle of attack of the keel and bringing it out of the stall.
